#### Abstract

Vascular sonography requires a basic understanding of statistical concepts used to evaluate exam efficacy. Statistical analysis, however, is often viewed as intimidating and dull. To make this subject less threatening and more interesting, our vascular ultrasound class investigated the prevalence of hemodynamically significant internal carotid artery (ICA) disease based on signs of the zodiac. Randomly selected carotid ultrasound patients were obtained from an accredited vascular laboratory database based on month and day of birth. Each sign of the zodiac was assigned 60 patients. Exam results were defined as (1) normal: bilateral < 50% ICA stenoses, or (2) abnormal: unilateral or bilateral  $\ge 50\%$  ICA stenosis. The Fisher exact test was used to compare normal and abnormal patient groups within each sign of the zodiac. The *P* value of < .05 was used to define statistical significance. A total of 720 patients were included in this analysis. Patients born under the sign of Gemini had significantly fewer numbers of abnormal stenoses than 6 astrological groups: Capricorn (*P* = .004), Virgo (*P* = .014), Libra (*P* = .007), Pisces (*P* = .026), Aries (*P* = .000), and Sagittarius (*P* = .001). Aquarius (*P* = .002), Gemini (*P* = .000), Pisces (*P* = .040), Cancer (*P* = .015), Scorpio (*P* = .002), and Leo (*P* = .022). Hemodynamically significant ( $\ge$ 50%) ICA stenoses were statistically more prevalent for carotid duplex patients born under the zodiac sign of Aries and significantly less prevalent under the sign of Gemini. While these results may be medically unimportant, this vascular ultrasound assignment helps students understand the value of statistical reporting and, in general, made statistical analysis more relatable and enjoyable.

statistics, education, carotid, stenosis, zodiac

# Purpose

The education and understanding of vascular ultrasound is increasingly reliant on referencing scientific research papers and journals rather than traditional textbook education. Inherent to the vascular ultrasound profession is a basic understanding of statistical concepts used to evaluate exam efficacy. Statistical analysis, however, is often viewed as intimidating and dull. A statement from a classmate exemplifies what I think many sonography students may feel: "Please God, no more statistics." To make this subject less threatening and more interesting, our vascular ultrasound class investigated the prevalence of hemodynamically significant internal carotid artery (ICA) disease by classifying patients based on their astrologic sign.

# Methods

Randomly selected carotid ultrasound patients were obtained from an accredited vascular laboratory database. Patients were selected based on the month and day of their birth corresponding to the astrological calendar, and 60 patients were assigned to each sign of the zodiac. Each patient's carotid duplex exam results were defined as (1) normal—bilateral < 50% ICA stenosis; maximum ICA peak systolic velocity (PSV) < 150 cm/s, or (2) abnormal—unilateral or bilateral  $\ge$  50% ICA stenosis; maximum ICA PSV  $\ge$  150 cm/s. The Fisher exact test using QuickCalcs GraphPad software was used to compare normal and abnormal patient groups within each sign of the zodiac. Statistical significance was defined as a *P* value of < .05.

## Results

A total of 720 patients with bilateral carotid duplex exams were analyzed, with 60 patients included in each of the 12 signs of the zodiac. Total number of normal (<50%) and abnormal

Figure 1. <50> internal carotid artery stenosis for signs of the zodiac.

 $(\geq 50\%)$  ICA stenosis with comparison analysis and designated *P* values for each of the 12 astrological signs are displayed in Figure 1.

Patients born under the sign of Aries had significantly greater numbers of abnormal ICA stenoses than 7 zodiacal groups: Taurus (P = .001), Aquarius (P = .002), Gemini (P = .000), Pisces (P = .040), Cancer (P = .015), Scorpio (P = .002), and Leo (P = .022).

Patients born under the sign of Gemini had significantly fewer numbers of  $\geq$ 50% stenoses than 6 astrological groups: Capricorn (*P* = .004), Virgo (*P* = .014), Libra (*P* = .007), Pisces (*P* = .026), Aries (*P* = .000), and Sagittarius (*P* = .007).

## Discussion

Whether you love or hate statistics, whether it puts you to sleep or makes you scream, an understanding of statistics remains a necessity for vascular sonographers in the 21st century. We must have at least a basic understanding of this subject so that we can critically evaluate scientific research inherent to the sonography profession. This assignment made me realize that a better understanding of statistical analysis helps clarify methodology and enhances the explanation and justification of the conclusions.

A greater appreciation of the statistical process assists in exposing sources of potential error and the reliability of the presented assumptions and principles. For example, our article discusses the prevalence of hemodynamically significant ICA disease based on patients' astrological signs, yet we made no adjustments for sample size or bias, including age, race, or gender. Moreover, more traditional risk factors known to increase the risk for developing carotid artery disease such as hypertension, hyperlipidemia, diabetes, obesity, smoking, peripheral artery disease, coronary artery disease, and family history were not examined as part of this study.

Sample size calculations vary. One blanket formula cannot be used for all study designs.<sup>1-3</sup> To prevent sample bias, an understanding of the study population from which the sample was drawn is required.<sup>3-5</sup> Native American and Caucasian individuals have the highest prevalence of carotid artery disease while African American males and Asian females have the lowest prevalence.<sup>6</sup> Carotid disease is more prevalent among men than women, and there is increased occurrence with age.<sup>7</sup> Uncontrolled variances and unbalanced study groups can result in skewed and implausible conclusions.

While our methodology in determining the prevalence of significant ICA stenoses based on the signs of the zodiac may be scientifically questionable and improbable, the actual handson study protocol of extracting relevant patient files from a large database, sorting them into specific categories, and evaluating results with the assistance of professional research sonographers brought to life the possibilities of using statistics in a real-world setting. Outside of the dry and often, unfortunately, dull academic rote learning environment, the gathering and interpretation of statistics became less threatening and far more interesting. For many students, this assignment was a turning point in their studies.

#### Acknowledgments

I express my gratitude to the sonographers and administrators of the Jobst Vascular Institute, Jobst Vascular Laboratory, and the Jobst Foundation for their encouragement and assistance. I acknowledge my classmates for their support and companionship, and a very special thanks to Abe Ettaher and Bob Scissons for more than I can list in this article.
